Petri Net Synthesis For Discrete

Petri Net Synthesis for Discrete Event Control of Manufacturing Systems develops two essential resource-sharing concepts: parallel and sequential mutual exclusions and theoretical results in Petri synthesis. A parallel mutual exclusion (PME) is defined to model a resource shared by independent distributed processes, and a sequential mutual exclusion is a sequential composition of PMEs, modeling a resource shared by sequentially-related processes.

A Petri net, also known as a place/transition net, is one of several mathematical modeling languages for the description of distributed systems. It is a class of discrete event dynamic system. A Petri net is a directed bipartite graph, in which the nodes represent transitions and places. The directed arcs describe which places are pre- and/or postconditions for which transitions. Some sources state that Petri nets were invented in August 1939 by Carl Adam Petri—at the age of 13—for the ...

Petri net - Wikipedia

Description. The Petri Net Toolbox is a software tool for the simulation, analysis, and design of discrete-event systems based on Petri Net models. Five types of Petri Net models are accepted: untimed, transition-timed, place-timed, stochastic, and generalized stochastic nets. The timed nets can be deterministic or stochastic.

However, for discrete event dynamic systems, effective design for real-world applications theory is lacking for real-world applications. Petri nets can be developed to fill this need. They have been used to model discrete event dynamic systems such as automated manufacturing systems and computer systems.

Continuous Petri nets can be seen as a relaxation of discrete models allowing more efficient (in some cases polynomial time) analysis and synthesis algorithms. Nevertheless computational costs can be reduced at the expense of the analyzability of some properties. Even more, some net systems do not allow any kind of continuization.
